About.—I investigate and address system security challenges through a data-driven approach that utilizes machine learning and deep learning methodologies. I have experience in a wide range of real-world services, including server-side online game transactions, root DNS servers, mobile payment transaction data, and vehicle system intrusion datasets.

Recently, my focus has been on vehicular system security as well as intrusion detection—a research area that requires urgent attention, given the severe consequences of compromised vehicle systems. Specifically, I have developed a standardized intrusion prevention system for connected vehicle systems to offer practical solutions to both industry and researchers in academia.

I have academic experience in teaching practical system hacking and defense techniques, such as reverse engineering, network hacking, smart car hacking, and attack defense strategies (*e.g.*, machine learning-based intrusion detection systems). I believe that is achieved through an in-depth understanding of traditional computer science and engineering concepts—including data structures, operating system concepts, system programming, data communications, and networking—so as to *really* understand security risks, threats, vulnerabilities, and proper countermeasures.
